

Truss Jib

Truss Jibs - A truss jib is actually used to be able to pick up and place trusses. It is an extended jib attachment which is equipped together with a triangular or pyramid shaped frame. Typically, truss jibs are mounted on equipment like a compact telehandler, a skid steer loader or a forklift using a quick-coupler accessory.

Older cranes have deep triangular truss jibs that are assembled from standard open structural shapes which are fastened utilizing bolts or rivets. On these style jibs, there are little if any welds. Each and every bolted or riveted joint is prone to rusting and thus needs frequent upkeep and inspection.

Truss jibs are made with a back-to-back arrangement of lacing members separated by the width of the flange thickness of another structural member. This particular design causes narrow separation between the smooth exteriors of the lacings. There is limited access and little room to clean and preserve them against rust. Numerous bolts become loose and rust in their bores and must be changed.
